Relative Definability and Models of Unary PCF

A. Bucciarelli, B. Leperchey, and V. Padovani

PFS, Université Denis Diderot
175 Rue du Chevaleret, 75013 Paris

Abstract. We show that the poset of degrees of relative definability in the Scott model of Unary PCF is non trivial, and that, nevertheless, the hierarchy of order extensional models of the language is reduced to a bottom element (the fully abstract model) and a top one (the Scott model itself).

1 Introduction

Finitary versions of PCF and related languages have been studied in the last decade, in order to settle the well-known “full abstraction problem” for the full language. In 1993, A. Jung and A. Stoughton [4] proposed the following crash test for a solution to that problem to be a “good” one: it should provide an algorithm for deciding observational equivalences for the finitary fragment of the language (i.e. the language whose unique ground type is bool, FPCF).

Shortly later, R. Loader proved that the observational equivalence of FPCF is undecidable [9]. An immediate corollary of this breakthrough result is that the problem of FPCF-definability in, say, the Scott model of PCF, is undecidable. Hence, relative FPCF-definability in that model is also undecidable.

The poset of degrees of relative definability is somehow related to the existence of hierarchies of (order extensional) models. The idea is the following: given a big model of FPCF, w.r.t. a natural notion of embedding, defined via a logical relation (see Sect. 2.4) an undefinable element $x$ of the model, and a logical relation $R_x$ which proves that $x$ is undefinable, one can:

- remove all elements of the model which are not invariant w.r.t. $R_x$,
- perform an extensional collapse on the remaining elements,

hence obtaining a new, smaller, model.

Let us consider, as an example, the following hierarchy of monotone functions $g_n : \text{bool}^n \rightarrow \text{bool}$ (generalizing a well-known example of first-order, stable and non sequential function, due to G. Berry)

$$g_n(x_1, \ldots, x_n) = \text{tt} \iff \exists y \in G_n \ x \geq y$$

where $G_n$ is the set of circular permutations of $(\bot, \text{tt}, \ldots, \text{tt, ff})$

For all $n \geq 3$, $g_n$ is FPCF-undefinable; moreover $g_{n+1}$ is FPCF-definable relatively to $g_n$, and the converse does not hold.
Now, for all \( n \), we define a logical relation \( R_n \) such that \( g_n \) (and hence all the \( g_{n-i} \)) is not invariant w.r.t. \( R_n \), and \( g_{n+1} \) (and hence all the \( g_{n+i} \)) is invariant w.r.t. \( R_n \). This relation \( R_n \) is an instance of “sequentiality relation” (see definition 2), and in Sieber’s terminology \( R_n = S^{n+1}_{\{1,\ldots,n\}\{1,\ldots,n+1\}} \), i.e., \( R_n \) contains, at ground type, the set of \((n+1)\)-tuples which are either constant or does contain an occurrence of \( \bot \) in one of the first \( n \) components.

Performing the two operations described above w.r.t. \( R_n \), yields a model which does not contain \( g_n \) and contains \( g_{n+1} \).

Hence, concerning FPCF, we have that:

1. The observational equivalence is undecidable.
2. The definability problem in the Scott model is undecidable.
3. The relative definability problem (in the Scott model) is undecidable, and the poset of degrees of relative definability is infinite.
4. There exist infinite hierarchies of standard, order extensional models.

Several authors have investigated restrictions on the syntax of FPCF which make observational equivalence decidable: V. Padovani has shown that this can be achieved by eliminating all non ground constants (the if-then-else in FPCF) [12]. Schmidt-Schauss [15] and independently, R. Loader [8], have proved that observational equivalence is decidable also for the “unary” version of PCF (a single ground type \( o \) with two constants \( \bot \) and \( \top \) and a “sequential convergence test” \( \land : o \rightarrow o \rightarrow o \)).

In a recent paper [5], J. Laird shows that Berry’s model of bidomains is universal for UPDF (using the listing algorithm devised by Schmidt-Schauss).

In this paper, we address the following questions:

1. Is the poset of degree of relative definability in the Scott model of UPDF trivial? (i.e. does it contain just the degree of definable functions, and the one of functions equivalent to the “parallel convergence test” \( \lor \))?
2. Is the hierarchy of (standard and order extensional) model of UPDF trivial? (i.e. does it contain just the Scott and the fully abstract model?)

Our first remark was that a positive answer to the first question implies a positive answer to the second one. Surprisingly enough, it turns out that the poset of degree is non trivial, and the one of models is trivial\(^1\).

The point is that, when applying the “collapsing” technique described above to the Scott model of UPDF in order to eliminate, say, the degree of \( \lor \), by picking up an appropriate logical relation (typically, Sieber’s \( S^3_{\{1,2\}\{1,2,3\}} \)) then all the other degrees collapse too, either in the first phase (elimination of non-invariant elements) or in the second one (extensional collapse of the invariant elements).

\(^1\) The fact that the poset of models is trivial has an alternative proof, simpler then ours, due to J. Laird [6], but less general. In fact we are able to apply our result also in order to reason about the hierarchy of models of FPCF (Sect. 4.4).
2 Preliminaries

We introduce the notion of relative definability, the language UPCF and its Scott model, and logical relations, that we use both to compare degrees of definability and models.

2.1 Degrees of Definability

Given an applied calculus $L$, a model $\mathcal{M}$ of $L$, and two elements $f \in \mathcal{M}^\tau$ and $g \in \mathcal{M}^\tau$, we say that $f$ is smaller than $g$ in the $L$-definability preorder of $\mathcal{M}$, $f \preceq^L \mathcal{M} g$, if there exists an $L$-term $M : \sigma \rightarrow \tau$ such that $[M]^L \mathcal{M} g = f$.

A degree of $L$-definability in $\mathcal{M}$ is an equivalence class of the equivalence relation associated with the preorder above, and degrees are partially ordered by $\preceq^L \mathcal{M}$. The poset of degrees always has a smallest element, namely the degree of definable elements.

Degrees of PCF-definability in the Scott-continuous model, often called degrees of parallelism have been studied for instance in [1], while degrees of PCF-definability in the model of strongly stable function (which could be called degrees of intensification) have been investigated in [2,10,11].

Of course, if $\mathcal{M}$ has the definability property w.r.t. $L$ (i.e. if any element of $\mathcal{M}$ is the denotation of some $L$-term), then the poset of degrees of $L$-definability in $\mathcal{M}$ is reduced to a singleton.

When the language and the model we refer to are clear from the context, we will omit “$L$” and “$\mathcal{M}$”, in the definition and notations above, and we will speak of “degrees of definability”, or even, when the model is order extensional, of “degrees of parallelism”. Moreover, we use the same symbols for the constants of $L$ and their denotations in $\mathcal{M}$.

In the rest of this section, we focus on Unary PCF. Nevertheless, all the definitions and results apply to FPCF too, changing appropriately the ground type and its standard interpretation.

2.2 Unary PCF

Unary PCF is an example of applied $\lambda$-calculus: its ground constants are $\bot$, $\top : o$, and the only first order constant is $\land : o^2 \rightarrow o$.

Let $\mathcal{M}$ be a standard model of UPCF, that is:

- $[o] = \{ \bot, \top \}$, $[\top] = \top$ and $[\bot] = \bot$,
- $[\sigma \rightarrow \tau]$ is a subset of $[\tau]^{|o|}$

We can define an extensional order $\leq$ on $\mathcal{M}$:

- At type $o$, $x \leq_o y$ iff $x = \bot$ or $x = y$,
- At type $\sigma \rightarrow \tau$, $f \leq_{\sigma \rightarrow \tau} g$ iff $\forall x \in [\sigma]$, $fx \leq_{\tau} gx$.

**Definition 1.** $\mathcal{M}$ is a standard order-extensional model if:
- $\mathcal{M}$ is a standard model,
- All functions are monotonic for the order $\leq$.

The Scott model $\mathcal{E}$ of UPFC is the standard, order extensional model where $\llbracket \sigma \rightarrow \tau \rrbracket = \{ f : \llbracket \sigma \rrbracket \rightarrow \llbracket \tau \rrbracket \mid f \text{ is } \leq\text{-monotonic} \}$, each $\llbracket \sigma \rrbracket$ being partially ordered by $\leq$.

### 2.3 Sequentiality Relations

This definition and the proposition are taken from [14].

**Definition 2.** If $A \subseteq B \subseteq \{1, \ldots, n\}$, $S^A_{A,B}$ is the set of tuples $(x_1, \ldots, x_n)$ such that either $\exists i \in A, x_i = \perp$ or $\forall i, j \in B, x_i = x_j$. A Sieber relation is a logical relation which is an intersection of a number of $S^i_A$ at base type.

**Proposition 3.** The Sieber relations are exactly the relations which contain the constants of UPFC.

The fundamental lemma of logical relations ensures that the denotation of any UPFC term, in any model, is invariant w.r.t. all Sieber relations.

### 2.4 Hierarchies of Models

**Definition 4.** Given two standard models $\mathcal{M}$ and $\mathcal{N}$, the relation $R_{\mathcal{M}, \mathcal{N}}$ is the only logical relation which is the identity at the base type.

**Definition 5.** A logical relation $R$ is functional if
\[
\forall \sigma, \forall f \in \llbracket \sigma \rrbracket^\mathcal{M}, \forall g, g' \in \llbracket \sigma \rrbracket^\mathcal{N}, f_R g \land f_R g' \implies g = g'
\]
If $R$ is functional and $x \in \llbracket \sigma \rrbracket^\mathcal{M}$, we write $R(x)$ for the only $y \in \llbracket \sigma \rrbracket^\mathcal{N}$ such that $x_R y$.

A logical relation $R$ is onto if
\[
\forall \sigma, \forall g \in \llbracket \sigma \rrbracket^\mathcal{N}, \exists f \in \llbracket \sigma \rrbracket^\mathcal{M}, f_R g
\]

**Definition 6.** A model $\mathcal{M}$ is smaller than a model $\mathcal{N}$ if $R_{\mathcal{N}, \mathcal{M}}$ is functional and onto. $\mathcal{M}$ and $\mathcal{N}$ are isomorphic if $\mathcal{M}$ is smaller than $\mathcal{N}$ and $\mathcal{N}$ is smaller than $\mathcal{M}$.

**Lemma 7.** Assume $R^\sigma$ is functional and onto. Let $z, z' \in \llbracket \sigma \rrbracket^\mathcal{E}$, $y \in \llbracket \sigma \rrbracket^\mathcal{M}$. If $y = R(x)$ and $y = R(x')$ then $y = R(x \land z')$. If $y \leq R(x)$ and $y \leq R(x')$ then $y \leq R(x \land z')$.

**Proof.** If $\sigma = \rho$, $R$ is the identity. Assume $\sigma$ is a functional type, and let $a$ be an argument of $z$ and $z'$. $R(xa) = yR(a) = R(x'a)$. By hypothesis, $R(xa \land z'a) = yR(a) \implies R((x \land z')a) = yR(a)$. Finally, we get $R(x \land z') = y$. The proof is the same for $\leq$.  \hfill $\square$
Lemma 8. If $R$ is functional and onto, there exists a total monotonic map $R^{-1}$ such that $\forall x \in [\alpha]^\mathcal{M}, x = R(R^{-1}(x))$.

Proof. Lemma 7 allows us to define $R^{-1}(y)$ as the smallest $x$ such that $R(x) = y$. $R^{-1}$ is monotonic: if $x \leq y$, $x \leq R(R^{-1}(x))$ and $x \leq R(R^{-1}(y))$. With lemma 7, we get $x \leq R(R^{-1}(x) \wedge R^{-1}(y))$, and the monotonicity of $R$ gives $R(R^{-1}(x)) \geq R(R^{-1}(x) \wedge R^{-1}(y))$. This yields $x = R(R^{-1}(x) \wedge R^{-1}(y))$, so $R^{-1}(x) \leq R^{-1}(x) \wedge R^{-1}(y)$, and finally $R^{-1}(x) \leq R^{-1}(y)$.

Proposition 9. If $\mathcal{M}$ and $\mathcal{N}$ are standard order-extensional models of UPCCF and $\mathcal{N}$ is fully abstract, $\mathcal{N}$ is smaller than $\mathcal{M}$

Proof. We write $R = R_{\mathcal{M}, \mathcal{N}}$. At ground type, $R$ is a bijection. Assume that $R$ is functional and onto at types $\sigma$ and $\tau$.

Assume $f R^{\sigma \to \tau} g$ and $f R^{\sigma \to \tau} g'$. Let $x \in [\sigma]^\mathcal{M}$. Since $R^\sigma$ is onto, there exists $y \in [\sigma]^\mathcal{N}$ such that $R(y) = x$. We get $gx = g(R(y)) = R(fy) = g'(R(y)) = g'x$, which entails $g = g'$: $R^{\sigma \to \tau}$ is functional.

Let $g \in [\sigma \to \tau]^\mathcal{N}$. Since $\mathcal{N}$ is fully abstract, there exists a closed term $G$ such that $[G]^\mathcal{N} = g$. By the fundamental lemma of logical relations

$$[G]^\mathcal{M} R^{\sigma \to \tau} [G]^\mathcal{N}$$

This yields $[G]^\mathcal{M} R^{\sigma \to \tau} g$: $R^{\sigma \to \tau}$ is onto.

3 Some Degrees in the Big Model of UPCCF

We know that the poset of degrees of UPCCF-definability in the Scott model has a smallest element $\bot_{de}$ (the degree of definable elements). A biggest degree $\top_{de}$ (the degree of the “parallel convergence test” $\Lambda xy. x \lor y$), also exists:

Lemma 10. All elements of the Scott model of UPCCF are definable relatively to $\Lambda xy. x \lor y$.

Proof. We make an induction on the types.

Let $f : \sigma_1 \to \ldots \to \sigma_n \to o$. Let $(x_{i1}, \ldots, x_{in})_{i=1\ldots n}$ be the trace of $f$ (the smallest tuples such that $f$ yields $\top$).

If $x : \sigma_i$, the function $\leq_x$ mapping $y$ to $\top$ if $x \leq y$ and to $\bot$ otherwise is definable: if $(a_{i1}, \ldots, a_{ik})_{i=1\ldots k}$ is the trace of $x$, and $a_{ij} = (A_{ij})$ (by hypothesis), then $\lambda y_1 \ldots y_{kj} ((\leq_{x_{i1}} y_1) \land \ldots \land (\leq_{x_{in}} y_n)) \lor \ldots \lor ((\leq_{x_{i1}} y_1) \land \ldots \land (\leq_{x_{in}} y_n))$ defines $\leq_x$.

One easily checks that $f$ is defined by

$$\lambda y_1 \ldots y_{nk} ((\leq_{x_{i1}} y_1) \land \ldots \land (\leq_{x_{in}} y_n)) \lor \ldots \lor ((\leq_{x_{i1}} y_1) \land \ldots \land (\leq_{x_{in}} y_n))$$

In the Scott model of Unary PCF, one can easily show that any first order function belongs either to the smallest degree (i.e. it is definable), or to the biggest one (i.e. it allows to (UPCCF)-define any other element of the model).
Lemma 11. If $\psi : \alpha^n \rightarrow o$ is undefinable, then there exists $u_1, \ldots, u_n$ where $u_i \in \{x, y, \top, \bot\}$, such that $[\lambda fxy.(fu_1 \ldots u_n)] \psi = \top$.

Proof. By hypothesis, $\psi$ is not a constant function. Suppose there is a unique minimal sequence $c \in \{\top, \bot\}^n$ such that $\psi(c) = \top$. Take $u_i = \top$ if $c_i = \bot$, $x_i$ otherwise. Then $[\lambda x_1 \ldots x_n.u_i \land \ldots \land u_n] = \psi$, a contradiction.

Let $c_1, c_2 \in \{\top, \bot\}^n$ be minimal distinct sequences such that $\psi(c_1) = \psi(c_2) = \top$. Take $u_i = x$ if $(c_1^i, c_2^i) = (\top, \bot)$, $y$ if $(c_1^i, c_2^i) = (\bot, \top)$, $d$ if $c_1^i = c_2^i = [d]$. Check that $[\lambda fxy.(fu_1 \ldots u_n)] \psi = \top$. □

In other words, all first order types possess the 2-DEG property. We show that 2-DEG is not preserved at higher types, by constructing two intermediate degrees.

Let $\phi \in \mathcal{E}(\alpha^3 \rightarrow \alpha^3)$ be the function defined by $$\phi(f) = \begin{cases} \lambda xyz. x \land y & \text{if } f = \lambda xyz. x \land y \\ f & \text{otherwise} \end{cases}$$

Proposition 12. $\bot_{deg} \prec \phi \prec \top_{deg}$.

Proof. First of all, $\phi$ is monotone since there is no element of $\mathcal{E}(\alpha^3 \rightarrow \alpha^3)$ strictly in between $\lambda xyz. x \land y$ and $\lambda xyz. x \land y \land z$.

Concerning $\bot_{deg} \prec \phi$, we are going to show that $\phi$ is non-invariant w.r.t. a particular UPCF-relation: $S^3_{\{1,2\} \{1,2,3\}}$. Let $f = \lambda xyz. x \land y$, $g = \lambda xyz. x \land y \land z$, and let us use $S$ as a shorthand for $S^3_{\{1,2\} \{1,2,3\}}$.

First of all, it is easy to see that $(f, g, g) \in S$, since whenever $(x_1, x_2, x_3), (y_1, y_2, y_3), (z_1, z_2, z_3) \in S$ are such that $f x_1 y_1 z_1 = \top$ and $g x_2 y_2 z_2 = \top$, then either $x_1 = x_2 = \top$ or $y_1 = y_2 = \top$. In the former case we conclude that $x_3 = \top$, in the latter that $y_3 = \top$; in both cases, $g x_3 y_3 z_3 = \top$, and hence $(f, g, g) \in S$.

Next we prove that the $\phi$-image of $(f, g, g)$ is not in $S$, and hence that $\phi$ is not definable.

Let $h = \lambda xyz. x \land y \land z$. The $\phi$-image of $(f, g, g)$ is $(f, h, h)$; the following diagram shows that $(f, h, h) \not\in S$:

$$
\begin{array}{ccc}
\top & \bot & \top \\
\top & \bot & \top \\
\bot & \top & \bot \\
\top & \bot & \top \\
\end{array}
$$

In order to show that $\phi \prec \top_{deg}$, we show that $\top_{deg} \not\prec \phi$. We prove by induction on $(n, m)$ that there is no normal $n$-long term $M$ with $n$ free occurrences of $f, m$ occurrences of $\land$, such that $[\lambda fxy.M] \phi = \top$:

- $[[\lambda fxy.x]] \phi \neq \top$,
- if $M = M_1 \land M_2$, then:
  - either $[[\lambda fxy.M_1]] \phi \bot = \top$ and $[[\lambda fxy.M_1]] \phi = \bot$,
or $[[\lambda fx. M_2] \phi] \perp \perp = \top$ and $[[\lambda fx. M_2] \phi] = \bot$.

- if $M = (f(x_1 z_2 z_3, w)) N_1 N_2 N_3$ where no $N_i$ contains an occurrence of $f$ and $[[\lambda fx. z_2 z_3, w]] \phi$ is undefined, then by lemma 11 there exists $(t, t, u, w_1, w_2, w_3) \in \{x, y, \top, \bot\}^5$ such that:

$$[[\lambda fx. w[t/x, t_2/y, u_1/z_1, u_2/z_2, u_3/z_3]] \phi] = \bot$$

Since all substituted terms are of ground type, the term in the left-hand side is in normal, $\eta$-long form, and contains $n - 1$ occurrences of $f$.

- if $M = (f P N_1 N_2 N_3)$ where $P, N_1, N_2, N_3$ contain no occurrences of $f$, then for all $(t, u) \in \{\top, \bot\}^2$ and for $P' = P[t/x, u/y]$, $N'_1 = N[t/x, u/y]$, we have:

$$[[\lambda fx. M] \phi] [t] [u] = \phi [[P'] [N'_1] [N'_2] [N'_3]]$$

$$= [[P'] [N'_1] [N'_2] [N'_3]] [t] [u]$$

$$= [[P N'_1 N'_2 N'_3]] [t] [u]$$

In other words $[[\lambda fx. M] \phi] = [[\lambda fx. (P N_1 N_2 N_3)] \phi] = \top$ where the normal form of $(P N_1 N_2 N_3)$ contains no occurrence of $f$.

By using $\phi$, we are now able to define a new degree, represented by a function $\Phi$ which moreover is $S$-invariant: let $\Phi \in \mathcal{E}^{(o^3 \rightarrow \omega) \rightarrow (o^3 \rightarrow \omega)}$ be the function defined by

$$\Phi(\psi) = \begin{cases} 
\exists x y. \top & \text{if } \psi > \phi \\
\exists x y. \bot & \text{if } \psi < \phi \\
\exists x y. \top & \text{if } \psi \not\leq \phi
\end{cases}$$

**Proposition 13.** The degrees of $\phi$ and $\Phi$ are incomparable.

**Proof.** First of all, it is easy to see that $\Phi$ is actually an element of $E$, i.e. a monotone function.

Concerning $\Phi \not\leq \phi$, it is enough to remark that, if $\Phi \not\leq \phi$, then $\exists x y. x \vee y \not\leq \phi$.

In order to show that $\phi \not\leq \Phi$, we prove that $\Phi$ is invariant w.r.t. $S_{\{1,2\}}(x_1, x_2) = S$ (and we conclude using the fundamental lemma of logical relations, since $\phi$ is not $S$-invariant).

This amounts to showing that whenever

$$\Phi \not\leq \phi$$

$$\psi_1 \psi_2 \psi_3$$

$$x_1 x_2 x_3 \in S$$

$$y_1 y_2 y_3 \in S$$

one has $(\psi_1, \psi_2, \psi_3) \not\in S$, i.e. that $\psi_1, \psi_2 \geq \phi$ and $\psi_3 \not\leq \phi$ entail $\psi_1, \psi_2, \psi_3 \not\in S$.

Now, we decompose $\psi_3$ in two (not mutually exclusive) cases, and prove $(\psi_1, \psi_2, \psi_3) \not\in S$ for both of them:
- case 1: $\psi_3(\Delta y z. x \vee y) \leq \Delta y z. x \vee y \vee z$.
  let $f = \Delta y z. x \wedge y$, $g = \Delta y z. x \vee y$, as before.
  \[
  \begin{array}{c}
  \psi_1 \psi_2 \psi_3 \\
  f \quad g \quad g \in S \\
  \top \quad \bot \quad \bot \in S \\
  \top \quad \bot \quad \bot \in S \\
  \top \quad \top \quad \bot \notin S
  \end{array}
  \]

- case 2: there exist $f_0 \in \mathcal{E}^{\omega \rightarrow \omega \rightarrow \omega \rightarrow \omega}$, $x_0, y_0, z_0 \in \mathcal{E}^\omega$ such that $\psi_3 f_0 x_0 y_0 z_0 = \bot$ and $f_0 x_0 y_0 z_0 = \top$ (remark that if both (case 1) and (case 2) do not hold, then $\psi_3 > \phi$). Let $f' \in \mathcal{E}^{\omega \rightarrow \omega \rightarrow \omega \rightarrow \omega}$ be the function defined by
  \[
  f' x y z = \begin{cases} 
  \top & \text{if } x \geq x_0, \ y \geq y_0 \text{ and } z \geq z_0 \\
  \bot & \text{otherwise}
  \end{cases}
  \]
  Remark that $f'$ is definable and $f' \leq f_0$. Showing that $(f', f', f_0) \in S$ is trivial. We can now conclude:
  \[
  \begin{array}{c}
  \psi_1 \psi_2 \psi_3 \\
  f' \quad f' \quad f_0 \in S \\
  x_0 \quad x_0 \quad x_0 \in S \\
  y_0 \quad y_0 \quad y_0 \in S \\
  z_0 \quad z_0 \quad z_0 \in S \\
  \top \quad \bot \quad \bot \notin S
  \end{array}
  \]

We can summarize the results of this section by the following diagram, showing a fragment of the poset of degrees:

\[
\begin{array}{c}
\top_{\text{deg}} \\
[\phi] \\
\bot_{\text{deg}} \\
[\Phi]
\end{array}
\]

4 Standard Order-extensional Models

In this section, we state a theorem about a fragment of the hierarchy of standard order-extensional models: all the models strictly greater than the bidomains model contain a weak version of the parallel or. We apply this result to UPCEF, and give some clues about FPCF.
4.1 Bidomains

**Definition 14.** We write \( x \uparrow y \) if \( x \) and \( y \) are bounded. A dI-domain \((D, \sqsubseteq, \perp)\) is a Scott domain such that:

- Each compact element has finitely many lower bounds,
- \( \forall x, y, z \in D, y \uparrow z \implies x \cap (y \cup z) = (x \cap y) \cup (x \cap z) \).

A stable function between two dI-domains \( X \) and \( Y \) is a Scott-continuous function \( f \) such that

\[
\forall x, y \in X, x \uparrow y \implies f(x \cap y) = f(x) \cap f(y)
\]

**Definition 15.** \((D, \leq, \sqsubseteq, \perp)\) is a bidomain if:

- \((D, \leq, \perp)\) is a Scott domain,
- \((D, \sqsubseteq, \perp)\) is a dI-domain,
- the identity between \((D, \leq, \perp)\) and \((D, \sqsubseteq, \perp)\) is continuous,
- \( x \) and \( y \) are bounded in \((D, \sqsubseteq, \perp)\) then \( x \land y = x \cap y \).

**Proposition 16.** The category of bidomains is cartesian closed.

**Proof.** We define \( D \Rightarrow D' \):

- \( f \in D \Rightarrow D' \) if \( f \) is stable for \( \sqsubseteq \) and continuous for \( \leq \) and \( \sqsubseteq \)
- \( f \leq g \) iff \( \forall x \in D, f(x) \leq g(x) \)
- \( f \sqsubseteq g \) iff \( \forall x, y \in D, x \sqsubseteq y \implies f(x) \sqsubseteq g(y) \)

\( \square \)

**Definition 17.** Let \( t \in [\alpha_1 \rightarrow \alpha_2 \rightarrow \ldots \rightarrow o]^M \). \( Tr(t) \) is the set of \( ((x_1, \ldots, x_n), y) \in ([\alpha_1]^M \times \ldots \times [\alpha_n]^M) \times [o]^M \) such that:

- \( y \neq \perp \)
- \( tx_1 \ldots x_n = y \)
- For any \( x'_i \in [\alpha_i]^M \), if \( \forall i, x'_i \sqsubseteq x_i \) and \( tx'_1 \ldots x'_n = y \), then \( \forall i, x'_i = x_i \).

Note that \( Tr(t) \subseteq Tr(u) \) entails \( t \subseteq u \).

4.2 Bidomains and \( \lor^- \)

\( \lor^- \) is a parallel function smaller than the usual parallel or:

**Definition 18.** Let \( \top \neq \perp \) be an element of the base domain. \( \lor^- \) is the function defined by:

\[
\lor^- xy = \begin{cases} 
\top & \text{if } x = \top \text{ or } y = \top \\
\perp & \text{otherwise}
\end{cases}
\]

Note that if a model of FPCF contains \( \lor^- \) or \( \lor^- \), it contains them both. Thus we speak of \( \lor^- \) meaning “any \( \lor^- \)”. For UPCF, \( \lor^- = \forall xy. x \lor y \).

First, we state a useful lemma:
Lemma 19. If domains of $\mathcal{M}$ and $\mathcal{B}$ are isomorphic for types smaller or equal to $\alpha \to \beta$, and $f : [\alpha]^\mathcal{M} \to [\beta]^\mathcal{M}$, is $\leq$-monotone and $\subseteq$-stable, then $f \in [\alpha \to \beta]^\mathcal{M}$.

Proof. We write $R = R_{\mathcal{M}, \mathcal{B}}$. If $a, b \in [\alpha]^\mathcal{M}$, we define $a \subseteq b \iff R(a) \subseteq R(b)$

Let us now assume that $f$ is $\leq$-continuous and $\subseteq$-stable. Since the domains of $\mathcal{B}$ are isomorphic to the domains of $\mathcal{M}$, we can define a function $\hat{f}$ between domains of $\mathcal{B}$. $\hat{f}$ is also $\leq$-continuous and $\subseteq$-stable: $\hat{f}$ is an element of $[\alpha \to \beta]^\mathcal{B}$.

As $R^\alpha \to^\beta$ is a bijection, we can use $R^{-1}$. By definition of $R^\alpha \to^\beta$,

$$\forall x \in [\alpha], (R^{-1}(\hat{f})x, \hat{f}R(x)) \in R^\beta$$

By definition of $\hat{f}$,

$$\forall x \in [\alpha], (fx, \hat{f}R(x)) \in R^\beta$$

Since $R^\beta$ is a bijection, $\forall x \in [\alpha], fx = R^{-1}(\hat{f})x$. We get $f = R^{-1}(\hat{f})$, which means that $f \in [\alpha \to \beta]^\mathcal{M}$. □

We can now proceed with the theorem:

Theorem 20. If a standard order-extensional model is strictly greater than the bidomains model $\mathcal{B}$, then it contains $\forall^\tau$.

Proof. Let $\mathcal{M}$ be a standard order-extensional model such that $\mathcal{B}$ is strictly smaller than $\mathcal{M}$. Let $\omega$ be a smallest type (for the type depth) such that $R_{\mathcal{M}, \mathcal{B}}$ does not define an isomorphism between $[\omega]^\mathcal{M}$ and $[\omega]^\mathcal{B}$.

Since $\mathcal{B}$ is smaller than $\mathcal{M}$ and $[\omega]^\mathcal{M} \neq [\omega]^\mathcal{B}$, there is a $\phi \in [\omega]^\mathcal{M}$ such that $\exists \psi \in [\omega]^\mathcal{B}, \phi R_{\mathcal{M}, \mathcal{B}} \psi$. As the argument and result domains are isomorphic, we can write $\phi \not\in [\tau]$, $\phi R_{\mathcal{M}} \psi$. Of course, $\omega \neq \phi$. Let us write $\omega = \sigma \to \tau$. Since $\phi$ is continuous for $\leq$, we have that $\phi$ is not stable for $\subseteq$. Either $\phi$ is not monotone for $\subseteq$, or there exist $f$ and $g$ bounded in $([\tau], \subseteq)$ such that $\phi(f \land g) \neq \phi f \land \phi g$.

We prove that $\forall^\tau$ is definable in each case.

Let us assume that $\phi$ is not $\subseteq$-monotone. We choose $f$ and $g$ such that $f \subseteq g$ and $\phi f \not\subseteq \phi g$. If $\tau = o$, we have $\phi f = \top$ and $\phi g = \bot$. But, since $f \subseteq g$ entails $f \leq g$, $\phi$ is not $\leq$-monotone. Thus, $\tau$ is functional: let us write $\tau = \tau_1 \to \ldots \to \tau_n \to o$.

As $\phi f \not\subseteq \phi g$, $Tr(\phi f) \not\subseteq Tr(\phi g)$. We choose $((y_1, \ldots, y_n), \top) \in Tr(\phi f) \setminus Tr(\phi g)$ (where $\top$ can be any element in $[\phi]$ except $\bot$) Since $\phi$ is $\leq$-monotone, $f \leq g$, and $\phi f y_1 \ldots y_n = \top$, $\phi g y_1 \ldots y_n = \bot$. Therefore, there is a $(x_1, \ldots, x_n), \top \in Tr(\phi g)$ such that $\forall i, x_i \subseteq y_i$. Since $((y_1, \ldots, y_n), \top) \not\in Tr(\phi g)$, there is an $i$ such that $x_i \not\subseteq y_i$, which entails $\phi f x_1 \ldots x_n = \bot$. We have chosen $f$, $g$, $x_i$ and $y_i$ such that:

- $\phi f x_1 \ldots x_n = \bot$,
- $\phi g x_1 \ldots x_n = \top$,
- $\phi f y_1 \ldots y_n = \top$. 

As \( f \subseteq g \), and by lemma 19, the function \( m : \sigma \rightarrow \sigma \) defined by \( m \downarrow = f \) and \( m \uparrow = g \) is in \( \mathcal{M} \). As \( x_i \subseteq y_i \) and by lemma 19, the function \( \chi_i : \sigma \rightarrow \sigma \) defined by \( \chi_i \downarrow = x_i \) and \( \chi_i \uparrow = y_i \) is in \( \mathcal{M} \). One easily checks that
\[
\lambda a b. \phi(\psi a)(\chi_1 b) \ldots (\chi_n b) = \forall \top
\]

Let us now assume that \( \phi \) is \( \subseteq \)-monotone, and that there exist \( f, g, h \) such that \( f \subseteq h, g \subseteq h \), and \( \phi(f \cap g) \neq (\phi f) \cap (\phi g) \). Since \( \phi \) is \( \subseteq \)-monotone, \( \phi(f \cap g) \subseteq (\phi f) \cap (\phi g) \), and we get \( \phi(f \cap g) \sqsubseteq (\phi f) \cap (\phi g) \). This yields:
\[
\phi(f \cap g) < (\phi f) \cap (\phi g)
\]
We can choose \( x_1 \ldots x_n \) (where \( n \) can be 0) and \( \top \in [\sigma] \) (\( \top \neq \bot \)) such that \( \phi(f \cap g) x_1 \ldots x_n = \bot \) and \( ((\phi f) \cap (\phi g)) x_1 \ldots x_n = \top \). We can define a stable function \( \psi \) by:
- \( \psi \bot \bot = f \cap g \),
- \( \psi \top \bot = f \),
- \( \psi \bot \top = g \),
- \( \psi \top \top = h \).

Being \( \leq \)-continuous and \( \subseteq \)-stable, \( \psi \) is in \( \mathcal{M} \). One easily checks that
\[
\lambda a b. \phi(\psi a b) x_1 \ldots x_n = \forall \top
\]

\( \square \)

4.3 Unary PCF

We apply the theorem to the case of UP CF.

**Proposition 21.** Any standard order-extensional model of UP CF is smaller than the Scott model \( \mathcal{E} \).

**Proof.** Let \( \mathcal{M} \) be a standard order-extensional model. We write \( R \) for \( R_{\mathcal{E}, \mathcal{M}} \).

At type \( \sigma \), \( R \) is a bijection. Assume that \( R^\sigma \) and \( R^\tau \) are functional and onto, and let us prove that \( R^{\sigma \rightarrow \tau} \) is also functional and onto. Seeing \( R \) as a partial function, we write \( R(x) \) for the only \( y \) such that \( x R y \). \( R^{-1} \) is the function defined in lemma 8 at types \( \sigma \) and \( \tau \).

Let \( f \in [\sigma \rightarrow \tau]^\mathcal{E} \), \( g, g' \in [\sigma \rightarrow \tau]^\mathcal{M} \) such that \( f R^{\sigma \rightarrow \tau} g \) and \( f R^{\sigma \rightarrow \tau} g' \). Let \( x \in [\sigma]^\mathcal{M} \). By definition of \( R^{\sigma \rightarrow \tau} \),
\[
g x = g(R(R^{-1}(x))) = R(f(R^{-1}(x))) = g'(R(R^{-1}(x))) = g' x
\]
Thus, \( R^{\sigma \rightarrow \tau} \) is functional.
Let $g \in [\tau \to \tau]^{\mathcal{M}}$. If $x$ has an image by $R$, we define $\hat{f}(x) = R^{-1}(g(R(x)))$. Since the domains of $\mathcal{E}$ are lattices\footnote{Apart from this, the proof would be valid for FPCF}, we can define

$$f(x) = \bigvee_{R^{-1}(y) \leq x} \hat{f}(R^{-1}(y))$$

The monotonicity of $R$ and $R^{-1}$ yields the monotonicity of $f$. If $x \in \sigma \mathcal{E}$, $R(fx) = g(R(x))$. As $R^\tau = \{(x, R(x))\}$, $f R^\tau$ = $g$. $R^\tau$ is onto. \hfill \qed

**Theorem 22.** The model $\mathcal{B}$ of bidomains of UP CF is fully abstract.

**Proof.** See[5] \hfill \qed

The following is an easy consequence of lemma 10:

**Lemma 23.** If $\forall^\tau$ is in $\mathcal{M}$, then $\mathcal{M} \approx \mathcal{E}$.

**Corollary 24.** There are only two standard order-extensional models of UP CF: $\mathcal{B}$ and $\mathcal{E}$.

**Proof.** Combine these results with theorem 20. \hfill \qed

### 4.4 Finitary PCF

We show that there are infinitely many degrees above $[\forall^{-}]$ and infinitely many models smaller than $\mathcal{E}$ that contain $\forall^{-}$.

Let us call $\forall^n$ the function of type $\sigma^n \to \sigma$ defined by:

$$\forall^n x_1 \ldots x_n = \begin{cases} t & \text{if } n \text{ of } n-1 \text{ of the } x_i \text{ are equal to } t \\ f & \text{if } x_1 = \ldots = x_n = f \\ \perp & \text{otherwise} \end{cases}$$

We write $x \land y = \text{if } x \text{ then } (\text{if } y \text{ then } t \text{ else } \perp) \text{ else } (\text{if } y \text{ then } \perp \text{ else } f)$. One easily checks that $\forall^n = \lambda x_1 \ldots x_n. \forall^{n-1} (x_1 \land x_2) x_3 \ldots x_n$, which entails $\forall^n \preceq \forall^{n-1}$. Let us prove that $\forall^n \preceq \forall^{n-1}$, with the $n$-ary relation $S^n$ defined by

$$S^n = S^n_{\{1\ldots n\}, \{1\ldots n\}} \cap \left( \bigcap_{A \subseteq \{1\ldots n\}-1} S^n_{A, A} \right)$$

As one can check, the tuples $(x_1, \ldots, x_n)$ in $S^n$ are exactly such that:

- there is no $i, j < n$ such that $x_i = t$ and $x_j = f$
- the tuple is not $tt \ldots tf$ nor $ff \ldots ft$.

First, $\forall^n$ is not invariant by $S^{n+1}$ as shown by:
\[\forall^n \forall^n \forall^n \ldots \forall^n \forall^n \begin{array}{c} \downarrow \ t \ t \ldots \ t \ f \\ t \ t \ldots \ t \ f \\
 t \ t \ldots \ t \ f \\
 \vdots \end{array} \]

Let us now prove that \( \forall^n \) is invariant by \( S^n \). Then we conclude with the fundamental lemma of logical relations. Let \( x_{i,j} \) and \( y_i \) such that:

\[\begin{array}{c}
\forall^n \ldots \forall^n \\
x_{11} \ldots x_{1n} \\
\vdots \\
x_{1n} \ldots x_{nn} \\
y_1 \ldots y_n
\end{array}\]

and \((y_1, \ldots, y_n) \notin S^n\).

- If there exist \( i, i' < n \) such that \( y_i = t \) and \( y_{i'} = f \) then for all \( j \) but one, \( x_{ij} = t \) and \( x_{i'j} = f \), which entails \((x_{1j}, \ldots, x_{nj}) \notin S^n\).
- If \( \forall i < n, y_i = t \) and \( y_n = f \), one can check that there exists a \( j_0 \) such that \( \forall i < n, x_{ij} = t \). Since for all \( j \), \( x_{nj} = f \), \((x_{1j}, \ldots, x_{nj}) \notin S^n\).
- If \( \forall i < n, y_i = f \) and \( y_n = t \), for all \( j \) but one that \( \forall i < n, x_{ij} = f \) and \( x_{nj} = t \), which entails \((x_{1j}, \ldots, x_{nj}) \notin S^n\).

Note that for \( n \geq 3 \), \( \forall^n = \lambda x y, \forall^n t \ldots t x y \), hence we have defined a sequence of undefinable elements of \( \mathcal{E} \):

\[\forall^n \prec \ldots \prec \forall^4 \prec \forall^3 \prec \forall^2 = \forall\]

These elements being first-order functions, they cannot vanish with an extensional collapse. Thus, we have defined an infinite hierarchy of standard order extensional models of FPCF:

\[\ldots \subset \mathcal{E}^4 \subset \mathcal{E}^3 \subset \mathcal{E}\]

These models are not greater than \( \mathcal{B} \), but there might be corresponding models above \( \mathcal{B} \).

5 Conclusion

We have shown that the poset of degrees of parallelism in the Scott model of UPCF is non-trivial, and that the poset of extensional models of the language is reduced to the fully abstract and the Scott ones.

Some open questions arise naturally:
Decidability of the definability (and relative definability) problem in the Scott model of UPWF.
- Existence of infinitely many degrees of relative definability in the Scott models of UPWF.

A broader framework for this work is the study of the three related issues below\(^3\) for a given extensional, finitary applied\(\lambda\)-calculus \(L\), in order to explore the boundary decidable/undecidable with respect to the set of constants of \(L\).

(a) Decidability of the definability (and relative definability) problem in the Scott model.
(b) Existence of a (finitary and “non-syntactic”) fully abstract model.
(c) Decidability of the observational equivalence.

For FPCF, we know that (c), and hence (a) and (b), are false [9].
For UPWF, (b) is true [5] and (a) open.
For the simply typed\(\lambda\)-calculus without constants (replacing “Scott model” with “full set-theoretic model”) (c) is true [12], (a) false [7,3], (b) open.
For finitary, parallel PCF, (a) is true [13].
